Macintosh LC 575: Proper Way to Awaken Dimmed Display (9/94)

=======================================================================

Article Created: 29 September 1994

TOPIC -----------------------------------------------------------

I set the Screen control panel on my Macintosh LC 575 to dim the screen to save
energy.  I press the mouse button (without moving the mouse or touching the
keyboard) to wake up the computer and it freezes up.

The mouse still moves and keyboard commands work, however I cannot use the mouse
to select anything, it's as if the mouse button has been disabled.

What's causing this or how can I workaround it?

DISCUSSION -------------------------------------------------------

It is best to awaken the computer by moving the mouse or pressing a key on the
keyboard rather than pressing the mouse button.
